ACKNOWLEDGEMENTS

The authors would like to acknowledge the technical support provided by Pat Simmons and Phyllis Workman for glass fabrication, and Dave Best, Whitney Riley, and Beverly Wall for the chemical analysis required for this study.

EXECUTIVE SUMMARY

The objective of this study was to determine a sulfate solubility limit in glass for Sludge Batch 7b (SB7b). The SB7b composition projection provided by Savannah River Remediation (SRR) on May 25, 2011 was used as the basis for formulating glass compositions to determine the sulfate limit. Additions of Na₂O to the projected sludge composition were made by the Savannah River National Laboratory (SRNL) due to uncertainty in the final concentration of Na₂O for SB7b, which is dependent on washing effectiveness and the potential need to add NaOH to ensure an acceptable projected operating window. Additions of 4, 6, and 8 wt % Na₂O were made to the nominal May 25, 2011 composition projection. An updated SB7b composition projection was received from SRR on August 4, 2011. Due to compositional similarities, no additional experimental work using the August 4, 2011 compositions was considered to be necessary for this study.

Both Frit 418 and Frit 702 were included in this study. The targeted sulfate (SO₄²⁻) concentrations of the study glasses were selected within the range of 0.6 to 0.9 wt % in glass. A total of 52 glass compositions were selected based on the compositional variables of Na₂O addition, Actinide Removal Process (ARP) stream addition, waste loading, frit composition, and sulfate concentration.

The glasses were batched, melted, and characterized following SRNL procedures. Visual observations were recorded for each glass after it cooled and used as an indicator of sulfur retention. Representative samples of each of the glasses fabricated were subjected to chemical analysis to determine whether the targeted compositions were met, as well as to determine the quantity of sulfate that was retained after melting. In general, the measured composition data showed that there were only minor issues in meeting the targeted compositions for the study glasses, and the measured sulfate concentrations for each study glass were within 10% of the targeted values.

The results for the SB7b glasses fabricated with Frit 418 showed an apparent trend of increasing sulfate retention with increasing Na₂O additions to the 5/25/11 sludge projection. This trend appears contradictory to other recent studies of sulfate retention in Defense Waste Processing Facility (DWPF) type glasses. Additional apparent contradictions to this trend were found in the data collected in the present study. Overall, the results for the SB7b sulfate study glasses with Frit 418 and the 5/25/11 projection with Na₂O additions showed that subtle changes in this complex glass composition impacted the degree of sulfate retention. These results do however provide confidence that a 0.6 wt % sulfate limit in glass is warranted for Frit 418 with the SB7b compositions evaluated in this study. The results for the SB7b glasses fabricated with Frit 702 are consistent with those of the previous SB7a study in that Frit 702 allowed for higher sulfate retention as compared to Frit 418 for the same sludge compositions.

It is recommended that the DWPF implement a sulfate concentration limit of 0.6 wt % in glass for SB7b processing with Frit 418. If a higher than projected sulfate concentration is measured when SB7b processing begins (i.e., if a sulfate concentration higher than 0.6 wt % becomes necessary to achieve targeted waste loadings), DWPF should consider a transition to Frit 702. The sulfate limit could likely be raised to 0.8 wt % by transitioning to this frit. However, if DWPF considers transitioning from Frit 418 to Frit 702, additional glasses should be fabricated to confirm this higher limit due to the issues with incorrect B₂O₃ concentrations for some of the glasses made with Frit 702 in this study. There are several factors other than sulfate retention that must also be carefully considered prior to changing frit compositions.

1.0 Introduction

Sulfate in high level waste (HLW) from the Savannah River Site (SRS) Tank Farm can partition among at least three paths as it is processed at the Defense Waste Processing Facility (DWPF): (1) incorporation into the glass waste form, (2) volatilization and subsequent capture by the off gas system during melting, and (3) formation of a separate, sulfate-rich salt phase on the surface of the molten glass pool. The main concern for the DWPF when processing a high sulfate concentration feed is the formation of a sulfate-rich molten salt phase on the surface of the glass pool, which can have multiple adverse effects. For example, the presence of this low viscosity melt phase on the surface of the glass pool increases corrosion rates of the materials of construction (e.g., the off-gas system, refractories, and melter top head components). A sulfate concentration limit was implemented in the Product Composition Control System (PCCS) to avoid these issues. For Sludge Batch 1A, 1B, and Sludge Batch 2, the sulfate solubility limit was 0.4 wt % in glass.^{1,2} However, because of the increased sulfate concentrations in Sludge Batch 3 (SB3) due to the addition of excess material streams from the canyons and desire for less sludge washing, testing was conducted to determine whether the sulfate solubility limit could be increased to minimize washing of SB3 while achieving the desired waste loading. Based on sealed-crucible studies and Slurry-fed Melt Rate Furnace (SMRF) runs, the limit was raised to 0.6 wt % SO_4^{2-} in glass specifically for SB3 with Frit 418.³ Sludge Batch 4 (SB4),⁴ Sludge Batch 5 (SB5),⁵ Sludge Batch 6 (SB6),⁶ and Sludge Batch 7a (SB7a)⁷ were also examined on a batch by batch basis, and a 0.6 wt % SO_4^{2-} solubility limit in glass was recommended for each of these sludge batches. However, the sulfate limit in PCCS remains at 0.4 wt % in glass, and therefore any higher limit has to be confirmed for each new sludge batch. The current task was to determine a sulfate solubility limit in glass for the next sludge batch to be processed at DWPF, Sludge Batch 7b (SB7b), coupled with Frit 418 and Frit 702.

This study was performed in response to a Technical Task Request⁸ and followed a Task Technical and Quality Assurance Plan.⁹

2.0 Experimental Procedure

2.1 SB7b Composition Projections

Sludge composition projections for SB7b were provided by Savannah River Remediation (SRR)^a and were used as the basis for formulating glass compositions to determine the sulfate limit for SB7b. Table 2-1 provides the sludge composition projection from SRR, referred to as 5/25/11. This projection was identified by SRR as a bounding case for the SB7b blend with the Tank 40 SB7a heel remaining after an assumed processing rate of one Sludge Receipt and Adjustment Tank (SRAT) transfer every four days and a targeted SB7a waste loading (WL) of 40%. In other words, the 5/25/11 SB7b composition projection assumed that a smaller heel of SB7a would be present in Tank 40 at the time the SB7b batch from Tank 51 would be transferred into Tank 40 to constitute the SB7b blend. This is conservative from a sulfate concentration perspective since SB7b is projected to be higher in sulfate than is SB7a. The Savannah River National Laboratory (SRNL) calculated the compositional impact of the Actinide Removal Process (ARP) stream¹⁰ to develop the additional projection shown in Table 2-1.

Additions of Na_2O to the projected sludge composition were made due to uncertainty in the final concentration of Na_2O for SB7b, which is dependent on washing effectiveness and the potential need to add NaOH to ensure an acceptable projected operating window. Additions of 4, 6, and 8

^a The SB7b composition projection was received via email from H. B. Shah on May 25, 2011. See SRNL-NB-2010-00108, page 134 for further detail.

wt % Na₂O were made to the nominal 5/25/11 composition projection and the remaining components were normalized to give a total of 100 wt %, as shown in Table 2-1. ARP adjusted compositions were calculated for each of these additional projections.

Also included in Table 2-1 is a SB7b composition projection received from SRR near the end of the sulfate retention study.^a This projection is labeled 8/4/11 and considered the analyzed composition of SB7a in Tank 40 (i.e., the Waste Acceptance Product Specification sample). The 8/4/11 projections with and without the addition of the ARP stream are very similar to the 5/25/11 projections with 4 wt % Na₂O added. Note however that the projected sulfate concentration is considerably lower in the 8/4/11 projections. Given the overall compositional similarities and lower projected sulfate concentrations, no additional experimental work was considered to be necessary using the 8/4/11 compositions.

^a A revised SB7b composition projection was received via email from D. W. McIlmoyle on August 4, 2011. See SRNL-NB-2010-00108, page 164 for further detail.

*Indicates addition of Na₂O to the composition projection followed by normalization of the other components to 100 wt %. For example, +4 indicates a 4 wt % addition to the projected concentration of Na₂O. ARP additions were calculated following the respective Na₂O additions.

2.2 Glass Composition Selection

The sludge compositions in Table 2-1 based on the 5/25/11 projection were used to develop targeted glass compositions for the SB7b sulfate retention study. Waste loadings of 36 and 40% were considered to be of interest for DWPF processing of SB7b. Frit 418 was ultimately recommended for SB7b processing.¹¹ Frit 702 was initially recommended for SB7b because of the concern that a higher sulfate limit would be needed, and was later suggested as an alternative option to Frit 418 should sulfate concentrations in SB7b be found to be higher than anticipated.¹¹ Therefore, both Frit 418 and Frit 702 were included in this study. The nominal compositions of these frits are provided in Table 2-2.

Table 2-2. Nominal Frit Compositions (wt %).

Frit ID	B ₂ O ₃	Li ₂ O	Na ₂ O	SiO ₂
418	8	8	8	76
702	8	10	6	76

Further review of Table 2-1 shows that the 5/25/11 projection with ARP added and no additional Na₂O has the highest sulfate concentration at 1.95 wt %. This is equivalent to 0.78 wt % sulfate in glass at an assumed WL of 40% (assuming full retention in glass). The sulfate concentration in the 8/4/11 projection with ARP added is reduced to 1.55 wt %, or 0.62 wt % in glass at 40% WL. The targeted sulfate concentrations of the study glasses were therefore selected within the range of 0.6 to 0.9 wt %.

A total of 52 glass compositions were selected based on these variables (i.e., Na₂O addition, ARP addition, WL, frit composition, and sulfate concentration), as displayed in Table 2-3. The sludge compositions were renormalized without ThO₂, U₃O₈, and some of the very minor components^a as the targeted glass compositions were determined. The targeted compositions for all of the study glasses are included as Table A-1 in Appendix A.

^a The targeted glass compositions also excluded RuO₂, Cl, F, and I. The omission of these components is consistent with previous studies that established the 0.6 wt % sulfate limit for sludge processing and is not expected to impact the outcome of the study.

Table 2-3. Selected Glass Compositions for the SB7b Sulfate Retention Study.

2.3 Glass Fabrication

Glasses were batched and melted following the SRNL procedures.^{12,13} The glasses were prepared from the proper proportions of reagent grade oxides, carbonates, boric acid, and salts in 100 g batches. The raw materials were thoroughly mixed and placed into 95% platinum-5% gold, 300 ml crucibles and covered with loose fitting lids. The crucibles were placed into an electrically heated furnace at the target melt temperature of 1150 °C. After an isothermal hold at 1150 °C for one hour, the crucibles were removed from the furnace and quenched in shallow pans of water with the glass remaining in the crucible. Visual observations were recorded for each glass after it cooled and used as an indicator of sulfur retention. Specifically, the glasses in the cooled crucibles were examined for evidence of a yellow or white sulfur salt layer on the surface of the cooled glass, or the presence of undissolved batch, spinels, large crystals, etc. When a visible sulfate salt layer was visible on the surface of a cooled glass, it was assumed that the targeted sulfate concentration surpassed the solubility limit for that particular glass composition. If there was no visible evidence of a sulfur salt layer, the targeted sulfate concentration was concluded to have remained below the sulfur solubility limit for that particular glass composition. Visual observations were supported by chemical composition analyses, as described in the following section.

2.4 Chemical Analysis

Representative samples of each of the glasses fabricated were subjected to chemical analysis to determine whether the targeted composition was met as well as to determine the quantity of sulfate that was retained after melting. Lithium-metaborate (LM) fusions were used in order to fully digest the glass for measurement of sulfur concentrations. Each glass was prepared in duplicate and all of the digested samples were analyzed by Inductively Coupled Plasma – Atomic Emission Spectroscopy (ICP-AES). The instrumentation was re-calibrated between the duplicate analyses.

3.0 Results and Discussion

Note that partial results of this study were provided previously in a memorandum to SRR.¹⁴ The complete results of the study are discussed in the following sections.

3.1 Measured Compositions

The measured compositions of each of the study glasses are presented along with the targeted values and the associated percent error in Table A-2 of Appendix A. The measured values for each oxide are the averages of the two elemental measurements from ICP-AES multiplied by the appropriate gravimetric factors. Values that were reported as being below the instrument detection limit were taken as one half of that detection limit as the average values were calculated. A review of Table A-2 shows that, in general, there were only minor issues in meeting the targeted compositions for the study glasses. In particular, two discrepancies were noted based on a comparison of the targeted and measured compositions. First, several of the glasses had measured B₂O₃ concentrations that were approximately 30% below the targeted values. These glasses are the SF7b-A series (see Table 2-3). The batch sheets and ICP-AES results for these glasses were reviewed a second time and no obvious cause for the low measured B₂O₃ concentrations was found. Therefore, these glasses will be included in the discussions that follow in this section. As will be noted later, the errors in meeting the targeted B₂O₃ concentrations for these glasses do not impact the outcome of the study for the glasses made with Frit 418, but do impact the results for the glasses made with Frit 702. Second, sulfur appears to have been omitted from one of the glass batches, as described below.

Table 3-1 provides the targeted and measured sulfate concentrations for each of the study glasses, along with the associated percent error. In general, the measured sulfate concentrations for each study glass were within 10% of the targeted values. Most of the measurements show a small loss of sulfate, which was likely due to both measurement error and minor volatility of sulfur. There are three glasses that exhibit further reduced sulfate concentrations. Glass SF7b-C-07 has a very low measured sulfate concentration, indicating that sulfur was unintentionally omitted from the batch for this glass. Glass SF7b-C-07 will therefore be omitted from further discussion. Two other glasses had differences between their targeted and measured sulfate concentrations that were larger relative to those of the rest of the study glasses. Glass SF7b-D-05 and glass SF7b-D-07 had measured sulfate concentrations that were about 25% and 37% below their targeted values, respectively. These two glasses will be included in the discussion below and their reduced sulfate concentrations will be noted.

Table 3-1. Targeted and Measured Sulfate Concentrations of the Study Glasses.

Glass ID	Frit ID	WL	Na ₂ O Addition (wt %)	ARP Addition	Targeted SO ₄ ²⁻ (wt %)	Measured SO ₄ ²⁻ (wt %)	Percent Error

3.2 Sulfate Retention

3.2.1 *Frit 418 Glasses*

Sulfate retention results for the glasses fabricated with Frit 418 will be discussed first since Frit 418 was ultimately recommended for SB7b processing.¹¹ The results for the SB7b sulfate study glasses with Frit 418 and the 5/25/11 projection with a 4 wt % Na₂O addition are shown graphically in Figure 3-1. The glass compositions are arranged by targeted sulfate concentration along the vertical axis and by both waste loading and ARP addition along the horizontal axis. By arranging the horizontal axis in this manner, the Na₂O concentration within the glasses increases from left to right for each targeted concentration of sulfate. A review of Figure 3-1 shows that no sulfate layer was observed on the surfaces of any of the glasses that targeted 0.6 wt % sulfate. Two of the glasses, those fabricated at 40% WL with and without the addition of ARP, had sulfate layers present at targeted sulfate concentrations of 0.7 wt %. All of the glasses fabricated at a targeted sulfate concentration of 0.8 wt % had a sulfate layer present. Note that these four glasses are part of the group mentioned earlier that have B₂O₃ concentrations that are about 30% lower than the targeted values. Based on the data shown in Figure 3-1 (i.e., the lack of a sulfate layer on any of the glasses that targeted 0.6 wt % sulfate and the presence of a sulfate layer on some of the glasses that targeted 0.7 wt % sulfate), the sulfate retention limit for this particular series of compositions is 0.6 wt %, and therefore the issue with B₂O₃ concentrations in the glasses targeting 0.8 wt % sulfate do not impact the results.

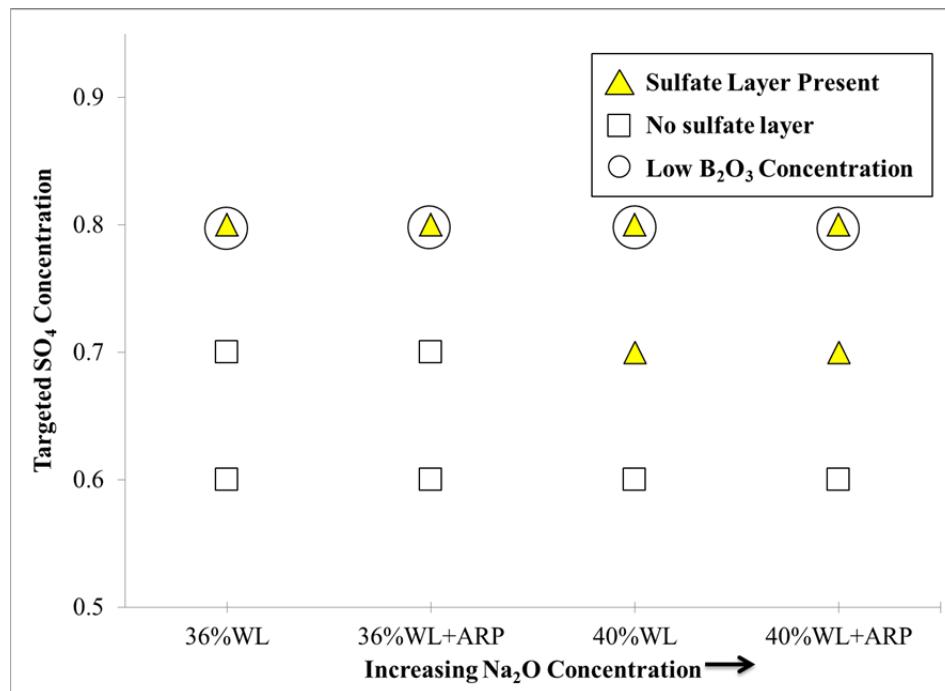

Figure 3-1. Results of the Sulfate Study Glasses with Frit 418 and the 5/25/11 SB7b Projection with 4 wt % Na₂O Added.

The results for the SB7b sulfate study glasses with Frit 418 and the 5/25/11 projection with a 6 wt % Na₂O addition are shown graphically in Figure 3-2. No sulfate layer was present on the glasses in this system with targeted sulfate concentrations of 0.7 wt %. The glasses that targeted 0.8 wt % sulfate in this system are part of the group with low B₂O₃ concentrations. One of these glasses, which targeted 40% WL, had a visible sulfate layer. A comparison of the results in Figure 3-2 with those in Figure 3-1 shows that the sulfate retention for Frit 418 increased to 0.7 wt % when the sodium addition to the 5/25/11 SB7b projection was increased from 4 wt % to 6 wt %.

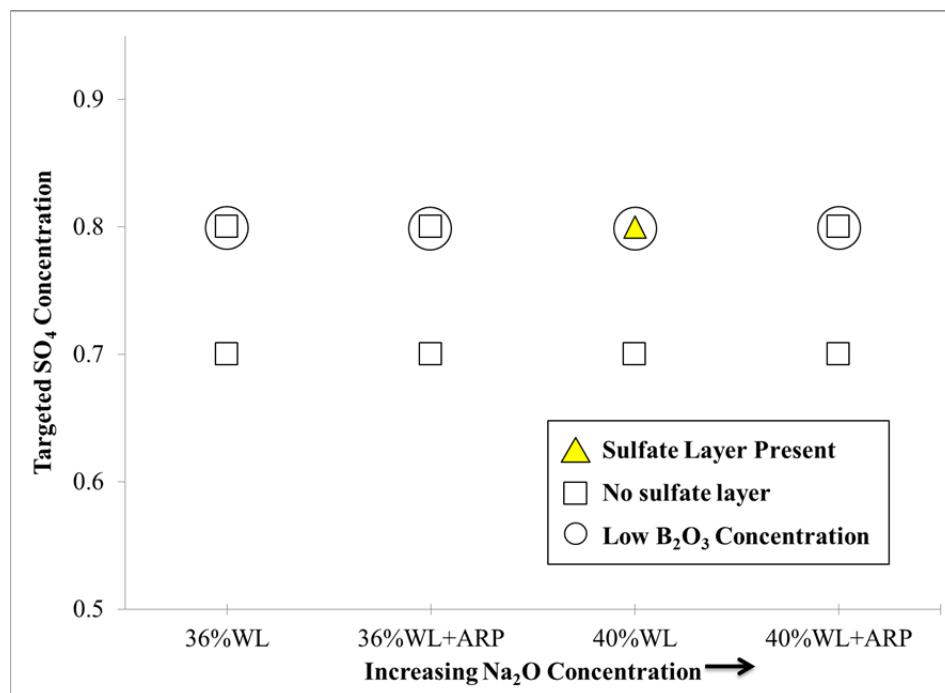

Figure 3-2. Results of the Sulfate Study Glasses with Frit 418 and the 5/25/11 SB7b Projection with 6 wt % Na₂O Added.

The results for the SB7b sulfate study glasses with Frit 418 and the 5/25/11 projection with an 8 wt % Na₂O addition are shown graphically in Figure 3-3. In this system, no visible sulfate layer was present on any of the glasses that targeted 0.8 wt % sulfate. At a targeted sulfate concentration of 0.9 wt %, the glasses that targeted 36% and 40% WL without the ARP addition had visible sulfate layers. Note also that, as described earlier, the two glasses that targeted 0.9 wt % sulfate and 36% WL with and without ARP have less sulfate than targeted (see glasses SF7b-D-05 and SF7b-D-07 in Table 3-1). Regardless of this issue, the sulfate retention limit for this system is 0.8 wt % based on the data shown in Figure 3-1.

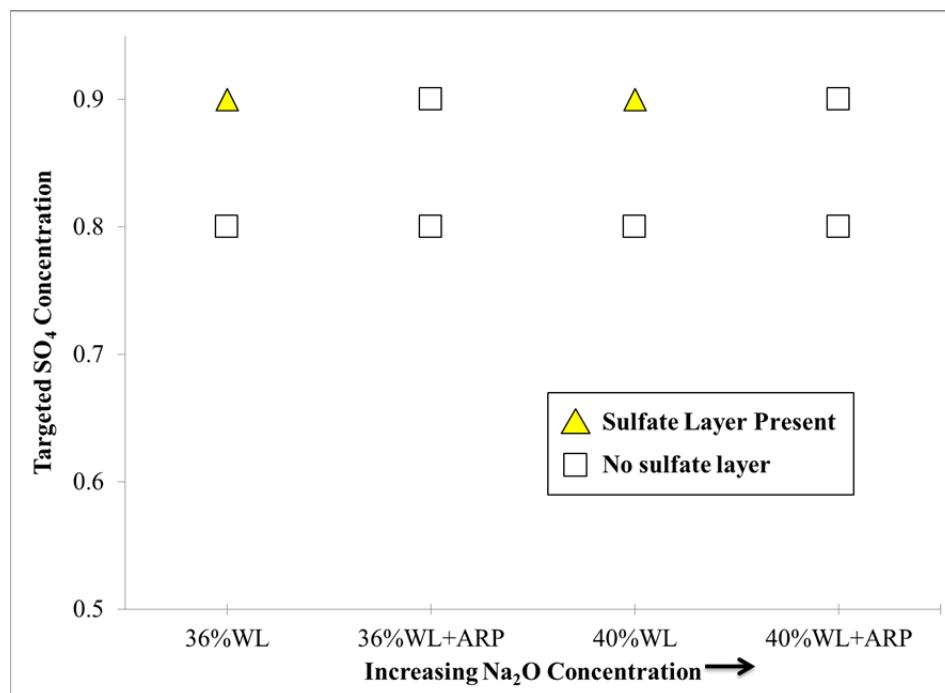

Figure 3-3. Results of the Sulfate Study Glasses with Frit 418 and the 5/25/11 SB7b Projection with 8 wt % Na_2O Added.

The data for the SB7b glasses fabricated with Frit 418 show an apparent trend of increasing sulfate retention with increasing Na_2O additions to the 5/25/11 projection. For this system, no sulfate layer was observed on the glasses:

- that targeted 0.6 wt % sulfate with a 4 wt % Na_2O addition,
- that targeted 0.7 wt % sulfate with a 6 wt % Na_2O addition, and
- that targeted 0.8 wt % sulfate with an 8 wt % Na_2O addition.

This trend appears contradictory to other recent studies of sulfate retention in DWPF type glasses.¹⁵ Additional apparent contradictions to this trend can be found in further review of the data presented here. For example, refer to the results in Figure 3-1 for the glasses that targeted 0.7 wt % sulfate. The glasses that targeted 36% WL with and without ARP had no visible sulfate layer. However, the glasses that targeted 40% WL with and without ARP (i.e., those that targeted higher Na_2O concentrations at the same targeted sulfate concentration^a) had visible sulfate layers.

Overall, the results for the SB7b sulfate study glasses with Frit 418 and the 5/25/11 projection with Na_2O additions show that subtle changes in this complex glass composition impacted the degree of sulfate retention. There doesn't appear to be a way to isolate and identify any particular component of the glass that was responsible for driving sulfate retention, at least using the methodology selected for this study. It may be that the nature of the method used in this study (visual analysis of glass compositions that are at or near the sulfur solubility limit) does not provide sufficient sensitivity. SRNL is currently evaluating alternative methodologies that may provide more insight into the mechanisms of sulfate retention in DWPF glasses. These results do

^a A review of the measured composition data for these glasses shows that the trends in targeted Na_2O concentrations are the same for the measured values. See Table A-2 in Appendix A.

however provide confidence that a 0.6 wt % sulfate limit in glass is warranted for Frit 418 with the SB7b compositions tested.

3.2.2 Frit 702 Glasses

Frit 702 was included in this study since it was suggested as a candidate for SB7b processing should higher than projected sulfate concentrations (i.e., higher than those of the 8/4/11 projection) be realized.¹¹ The sulfate concentrations of the 5/25/11 SB7b projections (Table 2-1) would have necessitated the use of Frit 702.

The results for the SB7b sulfate study glasses with Frit 702 and the 5/25/11 projection with a 4 wt % Na₂O addition are shown graphically in Figure 3-4. No visible sulfate layer was present on the glasses that targeted 0.8 wt % sulfate. All but one of the glasses that targeted 0.9 wt % sulfate had visible sulfate layers. Note however that the glasses that targeted 0.8 wt % sulfate are part of the group with low B₂O₃ concentrations. It is difficult to draw further conclusions from this system of glass compositions because of the issues with B₂O₃ concentrations.

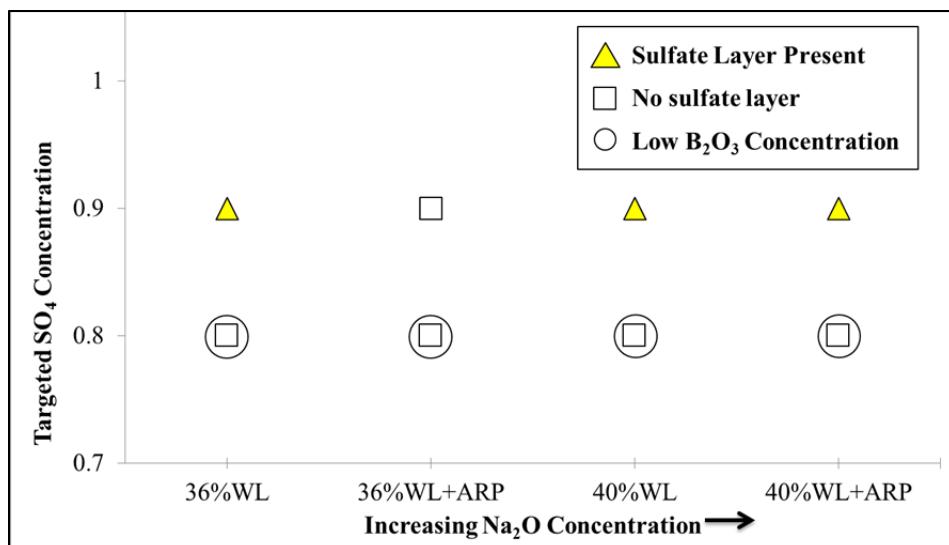

Figure 3-4. Results of the Sulfate Study Glasses with Frit 702 and the 5/25/11 SB7b Projection with 4 wt % Na₂O Added.

The results for the SB7b sulfate study glasses with Frit 702 and the 5/25/11 projection with a 6 wt % Na₂O addition are shown graphically in Figure 3-5. No visible sulfate layer was present on the glasses that targeted 0.8 wt % sulfate. Of the glasses that targeted 0.9 wt % sulfate, only the glass that targeted 40% WL (without ARP) had a visible sulfate layer. For this system, the sulfate limit would be 0.8 wt %, which is higher than that for the same SB7b composition with Frit 418 (see Figure 3-2, where the sulfate limit is 0.7 wt %). These results are consistent with those of the SB7a study⁷ in that Frit 702 allowed for higher sulfate retention as compared to Frit 418 for the same sludge compositions. However, this also contradicts the apparent trend noted earlier in the present study of increasing Na₂O concentrations being beneficial for sulfate retention, since Frit 702 has a lower Na₂O concentration than Frit 418. Again, these results show that subtle changes in this complex glass composition impact the degree of sulfate retention.

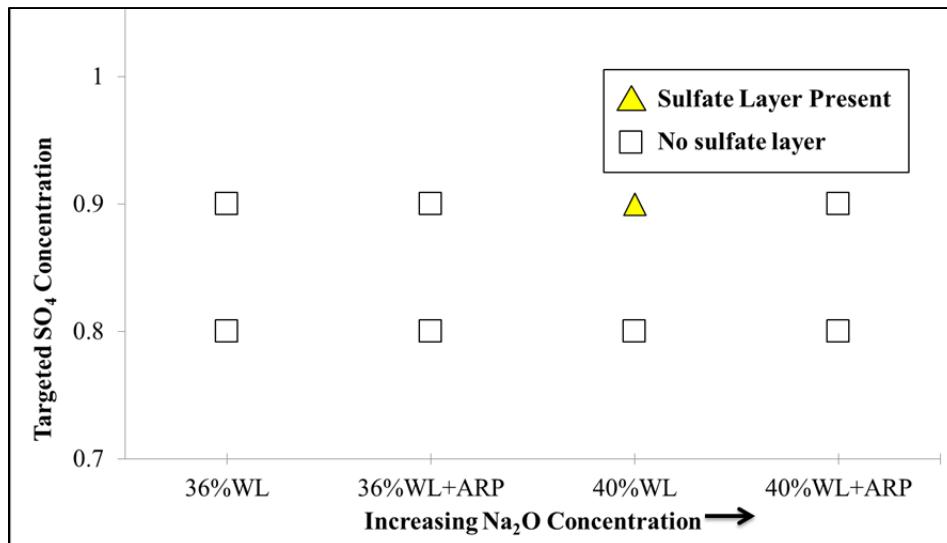

Figure 3-5. Results of the Sulfate Study Glasses with Frit 702 and the 5/25/11 SB7b Projection with 6 wt % Na_2O Added.

The results for the SB7b sulfate study glasses with Frit 702 and the 5/25/11 projection with an 8 wt % Na_2O addition are shown graphically in Figure 3-6. No visible sulfate layer was present on the glasses that targeted 0.8 wt % sulfate. Note that a data point is not shown for a targeted sulfate concentration of 0.8 wt % at 36% WL with ARP added. This composition was targeted by glass SF7b-C-07. The measured composition data for this glass showed that sulfur was omitted from the batch; therefore, this glass is not included in Figure 3-6 (refer to Section 3.1 and Table 3-1). Of the glasses that targeted 0.9 wt % sulfate, only the glass that targeted 40% WL (without ARP) had a visible sulfate layer. These results are very similar to those shown in Figure 3-5 for Frit 702, and are also similar to those shown in Figure 3-3 for Frit 418. In all three cases, the sulfate retention for the Frit 702 systems is 0.8 wt %. In general, a sulfate limit of 0.8 wt % appears to be warranted for Frit 702 with the SB7b compositions studied. Additional glasses should be fabricated to confirm this limit, due to the issues with incorrect B_2O_3 concentrations for some of the study glasses, should it become necessary to employ Frit 702 for DWPF processing of SB7b.

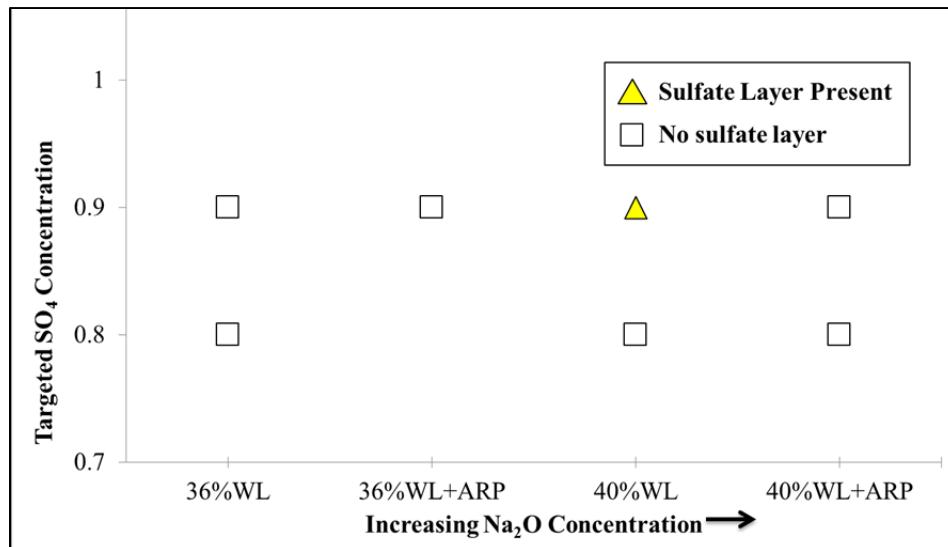

Figure 3-6. Results of the Sulfate Study Glasses with Frit 702 and the 5/25/11 SB7b Projection with 8 wt % Na_2O Added.

4.0 Summary

The objective of this study was to determine a sulfate solubility limit in glass for SB7b. The SB7b composition projection provided by SRR on May 25, 2011 was used as the basis for formulating glass compositions to determine the sulfate limit. Additions of Na_2O to the projected sludge composition were made by SRNL due to uncertainty in the final concentration of Na_2O for SB7b, which is dependent on washing effectiveness and the potential need to add NaOH to ensure an acceptable projected operating window. Additions of 4, 6, and 8 wt % Na_2O were made to the nominal 5/25/11 composition projection. SRNL calculated the impact of the addition of the ARP stream for the 5/25/11 SB7b projection as well as for each composition with Na_2O added. An updated SB7b composition projection was received from SRR on August 4, 2011. The 8/4/11 projections with and without the addition of the ARP stream are very similar to the 5/25/11 projections with 4 wt % Na_2O added. Note however that the projected sulfate concentration is considerably lower in the 8/4/11 projections. Therefore, no additional experimental work using the 8/4/11 compositions was considered to be necessary for this study.

Waste loadings of 36 and 40% were considered to be of interest for DWPF processing of SB7b. Both Frit 418 and Frit 702 were included in this study. Frit 418 was ultimately recommended for SB7b processing. Frit 702 was suggested as an option should sulfate concentrations in SB7b be found to be higher than anticipated. The targeted sulfate concentrations of the study glasses were chosen within the range of 0.6 to 0.9 wt %. A total of 52 glass compositions were selected based on these variables (i.e., Na_2O addition, ARP addition, WL, frit composition, and sulfate concentration).

The glasses were batched, melted, and characterized following SRNL procedures. Visual observations were recorded for each glass after it cooled and used as an indicator of sulfur retention. Representative samples of each of the glasses fabricated were subjected to chemical analysis to determine whether the targeted compositions were met, as well as to determine the quantity of sulfate that was retained after melting. In general, the measured composition data show that there were only minor issues in meeting the targeted compositions for the study glasses.

In particular, some of the glasses had measured B_2O_3 concentrations that were approximately 30% below the targeted values. The errors in meeting the targeted B_2O_3 concentrations for these glasses were found not to impact the outcome of the study for the glasses made with Frit 418, although they necessitate further experiments in order to establish a sulfate limit for Frit 702. In general, the measured sulfate concentrations for each study glass were within 10% of the targeted values. Most of the measurements showed a small loss of sulfate, which was likely due to both measurement error and minor volatility of sulfur. Glass SF7b-C-07 had a very low measured sulfate concentration, indicating that sulfur was unintentionally omitted from the batch for this glass. Glass SF7b-C-07 was therefore omitted from discussion. Two other glasses had differences between their targeted and measured sulfate concentrations that were larger relative to those of the rest of the study glasses. Glass SF7b-D-05 and glass SF7b-D-07 had measured sulfate concentrations that were about 25% and 37% below their targeted values, respectively. This result is not unexpected, since these glasses targeted sulfate concentrations of 0.9 wt % and sulfur volatility is more likely at increasing concentrations.

The results for the SB7b glasses fabricated with Frit 418 showed an apparent trend of increasing sulfate retention with increasing Na_2O additions to the 5/25/11 projection. This trend appears contradictory to other recent studies of sulfate retention in DWPF type glasses. Additional apparent contradictions to this trend can be found in the data collected in the present study. For example, the glasses made with Frit 418 that targeted 36% WL had no visible sulfate layer, while the glasses that targeted 40% WL for the same sludge compositions (i.e., those that targeted higher Na_2O concentrations at the same targeted sulfate concentration) did have visible sulfate layers. Overall, the results for the SB7b sulfate study glasses with Frit 418 and the 5/25/11 projection with Na_2O additions show that subtle changes in this complex glass composition impact the degree of sulfate retention. There doesn't appear to be a way to isolate and identify any particular component of the glass that is responsible for driving sulfate retention, at least using the methodology selected for this study. It may be that the nature of the method used in this study (visual analysis of glass compositions that are at or near the sulfur solubility limit) does not provide sufficient sensitivity. SRNL is currently evaluating alternative methodologies that may provide more insight into the mechanisms of sulfate retention in DWPF glasses. These results do however provide confidence that a 0.6 wt % sulfate limit in glass is warranted for Frit 418 with the SB7b compositions evaluated in this study.

The results for the SB7b glasses fabricated with Frit 702 were consistent with those of the previous SB7a study in that Frit 702 allowed for higher sulfate retention as compared to Frit 418 for the same sludge compositions. However, this also contradicts the apparent trend noted earlier in the present study of increasing Na_2O concentrations being beneficial for sulfate retention, since Frit 702 has a lower Na_2O concentration than Frit 418. Again, these results showed that subtle changes in this complex glass composition impact the degree of sulfate retention. In general, a sulfate limit of 0.8 wt % appears to be warranted for Frit 702 with the SB7b compositions evaluated in this study.

5.0 Recommendations

It is recommended that the DWPF implement a sulfate concentration limit of 0.6 wt % in glass for SB7b processing with Frit 418. If a higher than projected sulfate concentration is measured when SB7b processing begins (i.e., if a sulfate concentration higher than 0.6 wt % in glass becomes necessary to achieve targeted waste loadings), DWPF should consider a transition to Frit 702. The sulfate limit could likely be raised to 0.8 wt % by transitioning to this frit. Additional glasses should be fabricated to confirm this limit, due to the issues with incorrect B_2O_3 concentrations for

some of the glasses made with Frit 702 in this study. There are several factors other than sulfate retention that must also be carefully considered prior to changing frit compositions.
