PREFACE OR ACKNOWLEDGEMENTS

The authors would like to thank Madison Caldwell at Savannah River National Laboratory (SRNL) for her diligent and meticulous work in helping to complete ALTGLASS Version 3.0, as well as, Frances Williams (SRNL) for her outstanding efforts that helped bring the first versions of ALTGLASS to the international glass corrosion community. Without the help of both of these individuals, updates to the database would be much slower coming to fruition.

The development of the database was completed at SRNL under contract with the Department of Energy - DE-AC09-08SR22470 with Savannah River Nuclear Solutions (SRNS). Version 3.0 of the database was sponsored by the Department of Energy's Office of Environmental Management (DOE-EM). The compilation efforts of the original Versions 1.0-2.2 were cosponsored by DOE-EM and the Department of Energy's Fuel Cycle Research and Development (DOE-FCR&D) program.

EXECUTIVE SUMMARY

The Accelerated Leach Testing of GLASS (ALTGLASS) database is a collection of data from short- and long-term product consistency tests (PCT, ASTM C1285 A and B) on high level waste (HLW) as well as low activity waste (LAW) glasses. The database provides both U.S. and international researchers with an archive of experimental data for the purpose of studying, modeling, or validating existing models of nuclear waste glass corrosion. The ALTGLASS database is maintained and updated by researchers at the Savannah River National Laboratory (SRNL)[‡].

ALTGLASS provides the leachate compositions for corroding solutions including data for: Si, B, Ca, Li, Na, K, Al, Fe, Mo, Mg, Ti, Zn, and Zr. The database provides additional experimental information about each of the reported PCTs including:

- Glass Type (HLW or LAW)
- Test vessel type (Teflon or stainless steel)
- Test duration (days)
- Geometric surface area (SA) of initial glass product (m^2)
- Surface area-to-volume ratio (SA/V) (m^{-1})
- SA/V*time (days/m)
- Density (g/cm^3)
- Glass starting mass (g)
- Glass particle size (mesh)
- Leachant volume (L)
- Type of leachant (water, brine, etc.)
- Test temperature (°C)
- Final pH of leachant solution
- Secondary mineral phases formed during corrosion (mineral type, name)[†]
- Analytical method used to identify/study secondary mineral phases[†]
- Glass homogeneity prediction (THERMO™ model)
- Glass compositional state predictions
- Glass composition (wt.%)

The PCT-B test was recommended as an indicator of long-term glass dissolution behavior at surface area-to-volume ratios of 20 m^2/L and at 90°C.

The database was first compiled in FY2013 (ALTGLASS Version 1.0) and originally contained 2112 rows of data where each row represented the average of a duplicate or triplicate PCT response of a particular glass composition at a given test duration. The database, ALTGLASS Version 1.0, was updated to Version 2.0 in 2014 with the addition of 20 rows of data, and two updates, Versions 2.1 and 2.2, were issued to correct several minor input errors.

This newest version, ALTGLASS Version 3.0[‡], has been updated with an additional 503 rows of data representing PCT results from corrosion experiments conducted in the United States by the Savannah River National Laboratory, Pacific Northwest National Laboratory, Argonne National Laboratory, and the Vitreous State Laboratory (SRNL, PNNL, ANL, VSL, respectively) as well as the National Nuclear Laboratory (NNL) in the United Kingdom.

[†] Not available for all glass compositions reported in the database.
[‡] Electronic copies of ALTGLASS Version 3.0 can be obtained by contacting the database custodians:

1.0 Introduction

The Savannah River National Laboratory (SRNL), along with other laboratories within the DOE complex (e.g., ANL, PNNL, VSL) and international laboratories (e.g., NNL), have been conducting short to long-term sequences of static powder corrosion tests on high-level waste (HLW) and low-activity waste (LAW) using the short and long term Product Consistency Tests (PCT-A and PCT-B; ASTM C1285) [1]. These test sequences follow the evolution of the leachate solution composition so that the long term durability and corrosion mechanisms of the glasses can be assessed. SRNL has undertaken the task of compiling, combining, and preserving data from various national and international glass corrosion research programs into the Accelerated Leach Testing of GLASS (ALTGLASS) database.

The generally accepted model of glass corrosion [2,3], shown in Figure 1, divides the dissolution process into three stages marked by the different glass/gel corrosion mechanisms and solution interactions (Stage I, II, & III). Glasses typically undergo an initially rapid rate of corrosion, known as Stage I, during which several mechanisms are taking place nearly simultaneously relative to the duration of the latter stages [2]. Stage I corrosion mechanisms include hydrolysis, ion exchange, and interdiffusion. As the concentration of glass elements increases in the leachant solution, this initially rapid rate will start to slow and the glass corrosion process will transition into Stage II [3].

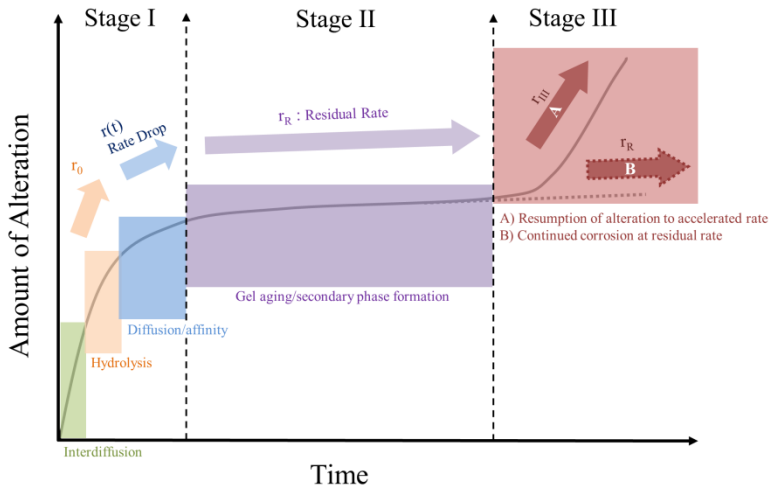

Figure 1: The generally accepted conceptual model demonstrating the various stages of corrosion a homogeneous waste glass will undergo in contact with aqueous solutions.

Characteristic Stage II corrosion is marked by a slow release of glass components into the leachate solution – the rate is typically orders of magnitude slower than the initial rate in Stage I. In Stage II, a pseudo-equilibrium state exists between the corroding glass/gel system and the contacting solution. Two hypotheses have been proposed for the rate-controlling mechanism driving the Stage II "residual" rate: 1) a thermodynamic affinity between the glass/gel and solution slowing the release of glass components into solution (e.g., aqueous silica saturation), and 2) a transport barrier is established by the formation of the gel layer, which hinders and/or prevents the diffusion of glass components into solution. It is probable that a coupled mechanism between those two hypotheses is actually controlling the Stage II dissolution [4].

Certain glass compositions will exhibit a sudden "resumption of alteration" after remaining in the pseudo-equilibrated Stage II regime for long times – this is known as Stage III corrosion. During Stage III, the concentration of elements such as B and Si in the leachant solution will increase at rates which are

comparable to the initial rate and significantly greater (1-4 orders of magnitude) than the residual rate. This "resumption of alteration" is marked by the formation of large quantities of highly crystalline mineral assemblages on the glass surfaces, which continue to increase in size as the glass dissolves at the accelerated rate.

Detailed knowledge of the corrosion behavior of a wide-ranging glass compositional space is required to develop an accurate radionuclide source term for a repository performance assessment (PA) model that encompasses the aforementioned corrosion phenomena and their effects on waste glass durability.

The ALTGLASS database was originally compiled in FY 2013 [5], and contained the results of static corrosion test duration sequences so that geochemical, thermodynamic, kinetic, and glass composition/structural approaches to the prediction of the long term glass durability can be studied on the national and international level. Version 1.0 of the database contained 2112 rows of data where each row represented an averaged duplicate or triplicate test response. Version 2.0 added 20 data sets [6] and Versions 2.1 and 2.2 corrected some minor input errors [6].

The database is openly available to national and international interests for the purpose of studying, modeling, or validating existing models of nuclear waste glass corrosion. For example, SRNL is currently applying aspects of informatics[†] to the database in order to correlate the evolution of corroding glass systems to observed corrosion phenomena. By utilizing the informatics methodologies, HLW and LAW glasses can be compared, contrasted, and grouped into categories that allow researchers to search for unifying compositional characteristics on a large, preexisting dataset, rather than designing and conducting expensive experiments sometimes lasting years or decades and only target a few compositions or experimental conditions. The ultimate goal of these efforts is to establish a link between deleterious corrosion mechanisms and original glass compositions.

This report documents Version 3.0 of the database, an update including 503 rows of new data, from tests conducted at several national and international sites including: SRNL, PNNL, VSL and NNL. The ALTGLASS Version 3.0 database is given in tabular form in this report (Appendix B - Table 11) and is electronically available to national and international modeling groups as a ".xlsx" file upon request.

2.0 Experimental Review

All of the static durability testing in the database was performed in accordance with the procedures set forth by ASTM C1285A or B, the Product Consistency Test (PCT). The PCT-A is a 7 day short term test conducted in a stainless steel digestion vessel with very specific experimental parameters. The PCT-B is less strictly parameterized in that many controls such as duration, particle size, and vessel type are variable. The PCT-B test was recommended as indicator of long-term glass dissolution behavior at surface area to volume ratios of 20,000 m^{-1} (20 m^2/L) and 90°C [7]. The ALTGLASS database contains data from two days to over 20 years of testing and is primarily for glasses tested in deionized water (ASTM Type I water). A few glasses that were tested in Yucca Mountain J13 and SRS E-Area groundwater are included for comparison to the studies in ASTM Type I water.

2.1 Static Test Details

The data in ALTGLASS was generated with the PCT – this ASTM protocol has two test methods: Test Method A and Test Method B. The details of each test method are given in Table 1, which is reproduced from Table 1 in the ASTM C1285 procedure [1].

[†] The term "informatics" refers to the science of information processing.

Table 1: Summary of PCT Test Methods A and B (from ASTM C1285-14)

	Test Method A	Test Method B
Type of Waste Form	Radioactive, Mixed Simulated, Hazardous	Radioactive, Mixed Simulated, Hazardous
Usage	During production for rapid analysis and for waste compliance*	Scoping tests; Crystalli-zation studies; Comparative waste form evaluation
Test Vessel	Unsensitized Type 304L stainless steel; vessels rated to> 0.5 MPa	Unsensitized Type 304L stainless steel or PFA TFE-fluorocarbon vessels rated to >0.5 MPa
Test Duration	7 days ± 2%	7 days ± 2% or varying times
Leachant	ASTM Type I water	ASTM Type I water or other solutions
Condition	Static	Static
Minimum Sample Mass	≥1 g	≥1 g
Particle Size	U.S. Standard ASTM −100 to +200 mesh (0.149 to 0.074 mm)	U.S. Standard ASTM −100 to +200 mesh (0.149 to 0.074 mm) or other sizes which are <40 mesh (0.420 mm)
Leachant Volume	10 ± 0.5 cm^3/g of sample mass	10 ± 0.5 cm^3/g of sample mass or other volume/sample mass
Temperature	90 ± 2°C	90 ± 2°C or other temperatures provided that any observed changes in reaction mechanism are noted
Atmosphere	Air	Air or CO_2 free air (optional)
Type of System	Closed to transport	Open to transport in PFA TFE-fluorocarbon; Closed to transport in stainless steel

The majority of data in ALTGLASS was derived at a leaching temperature of 90°C and in ASTM Type I water. Some of the data were collected at 200°C. Only one set of data was generated in J13 groundwater from the Nevada Test Site at 90°C and one set of data at 25°C in Savannah River Site (SRS) E-Area groundwater. The latter data were added to the database as the leachate data contained U concentrations which many of the other datasets did not. Other datasets in J13 groundwater were not included for the following reasons:

- Geochemical modeling in ASTM Type I water is fundamental for understanding glass dissolution mechanisms since all of the species in solution are generated by the glass.
    - Geochemical modeling in groundwater is complicated by the presence of Si and other elements that are common to the glass and the groundwater.
- Geochemical modeling of leachate concentrations in ASTM Type I water should be benchmarked before attempting to model more complicated leachate solution compositions.

The compositions of the J13 and E-Area groundwaters are given in Table 2.

Table 2: Compositions of J13 groundwater and SRS E-Area Groundwater

	J13 Yucca Mountain Groundwater[8]	SRS E-Area Groundwater[9]
Species	**Concentration (ppm)**	**Concentration (ppm)**
Aluminum	1.1	0.90
Boron	0.16	---
Calcium	5.1	0.41
Potassium	7.3	---
Iron	---	0.06
Lithium	0.05	---
Magnesium	0.39	0.71
Sodium	54	2.76
Silicon	46	4.75
HCO_3^-	120	---
F^-	3	---
Cl^-	9	2.71
NO_3^-	16	---
$SO_4^=$	35	6.15
pH	8.2	5.79

3.0 Test Parameters

The test parameters that govern the conduction of a PCT experiment were carefully chosen for a number of reasons, which are discussed in the following sections.

3.1 Glass Sample Parameters

For most of the samples in the ALTGLASS database, the crushed glass particle size was the nominal -100 to +200 mesh; although, the database does contain some glass entries with non-standard particle sizes shown in Table 3. For the majority of the entries in the ALTGLASS database, all of the test parameters that are relevant to geochemical modeling efforts are provided or can be calculated from the information given.

The surface area of the glass was calculated using equation (1):

$$SA = \frac{6m_g}{\rho d} \quad \left(cm^2\right) \tag{1}$$

Where m_g (g) is the mass of the glass, ρ (g/cm^3) is the glass density, and d (cm) is the diameter of an average particle in a given mesh size. Within the ALTGLASS database, measured density values are displayed in **boldface** font, and estimated density values[§] [10] are displayed in plain text. The average diameter of the particle sizes used for the different mesh ranges is given in Table 3, which were calculated using the arithmetic mean of the particle size range associated with each mesh size range [1].

[§] The value used for the "estimated density" was based on the density of an average HLW glass composition from DWPF.

Table 3: Average Particle Diameter for Various Mesh Sizes

Mesh Size Range	Range of Particle Diameters (cm)	Average Particle Diameter (cm)
-60 +80	0.0177-0.0250	0.0214
-100 +140	0.0105-0.0149	0.0127
-100 +200	0.0074-0.0149	0.0112
-200 +325	0.0044-0.0074	0.0059
-270 +400	0.0037-0.0053	0.0045

The surface area to volume of leachate, the SA/V parameter, is the surface area of glass calculated from equation (1) divided by the volume of the leachate solution – the units of the SA/V ratio are expressed in terms of the glass surface area exposed to a unit volume of corroding solution, e.g., m^2/L.

A time-normalized, SA/V parameter, SA/V*time, where time is the duration from t=0 to the aliquot sampling time, is also reported in the database. The dimension of this parameter is expressed in units of (m^2-day)/L. The SA/V and SA/V*t parameters provide a means to normalize results of experiments that were conducted with differing initial conditions as allowed by the PCT-B protocol.

Note that the SA/V values given in the database are calculated from the average particle size determined from the sieve range used in each study, which is the current method specified in the PCT procedure. For the SON68 and AFCI glasses studied and reported in Ebert et al. [11], the measured particle size from Microtrac analysis (after glass fines had been washed from the powder) was used to calculate the SA/V. Therefore, the SA/V given in the database does not match the values in Reference 11. Note that the method used to report the SA/V in the PCT procedure (ASTM C1285) is under discussion by the ASTM C26.13 committee.

All of the leachates were filtered through a 0.45 μm filter. Data from Reference 11 indicated that filtering with a 0.45 μm filter provided sufficient filtration to remove colloidal suspensions – viz., the same solution analyses results were obtained for filters with lesser pore sizes as were obtained with the 0.45 μm filters. Therefore, the ultrafiltration data is not tabulated separately in the database.

The maximum and minimum values of the test parameters are given in Table 4.

Table 4: Maximum and minimum of test parameters.

Parameter	Minimum	Maximum
Test Duration (days)	0.42	7426
SA/V (m^2/L)	1.1	39.1
(SA/V)·time (days/m)	3.9	30,938.7
Glass Density (g/cm^3)	2.373	3.004
Temperature (°C)	25	200

3.2 Compositional Characteristics and Indicators

There are currently no direct measurement techniques of a glass specimen that can quantify its chemical durability. Durability is measured through secondary measurements of leachate solutions, alteration layers, etc.; all of which are byproducts of durability and/or corrosion. However, one can make estimations of the corrosion resistance of a particular glass based on certain compositional "states", which are useful for classifying subsets of glasses based on structural properties. For instance, glasses that are predicted to be phase separated (φ-sep.) or potentially phase separated from compositional indicators are particularly susceptible to anomalous corrosion behavior [12].

Phase separation in glasses generally takes the form of two immiscible glass phases which differ in chemical composition, density, and surface tension. Usually one phase is more soluble than the other. Phase separation complicates modeling of glass durability as a function of composition because the composition of the overall glass is known but the compositions of the two immiscible phases are not known. Consequently, the performance of the overall glass is unpredictable and the long term durability of the glass cannot be modeled [12]. As such, information regarding the potential phase separation of a glass is useful in discriminating potentially anomalous durability responses caused by structural phenomena from an ALTGLASS data subset that is being used in modeling efforts. These compositional states are described in detail below.

Tovena, et al. [13] demonstrated that several HLW glass durability models [14-17] did not predict waste glass durability accurately when the composition of the waste glass contained > 15% B_2O_3 with little or no Al_2O_3. For these glasses all the models under-predicted the glass durability significantly. Tovena, et al. attributed the under-prediction to phase separation and complete dissolution of a borate rich phase in the glass when the Al_2O_3 content was insufficient to stabilize a glass against phase separation.

Jantzen, et al. [12] determined that phase separation could also occur in iron containing HLW glasses with insufficient Al_2O_3, i.e. Al_2O_3 concentrations in the region of 3-4 wt.%. It was also determined that the Al_2O_3-SiO_2-Fe_2O_3-Na_2O basalt quaternary system was a natural analog system for HLW iron containing glasses: the quaternary system depicts a region of phase separation at <4 wt.% Al_2O_3 [18]. In addition, glasses in the Na_2O-Al_2O_3-SiO_2 system are known to phase separate when the glasses contain less than 3 wt.% Al_2O_3 [19,20].

For these reasons, the durability model used by the Savannah River Site (SRS) Defense Waste Processing Facility (DWPF) [18] excluded the modeling of phase separated glasses by the development of a "phase separation discriminator" based on experimental data for both homogeneous and phase separated glasses. This discriminator methodology was carried over into the construction of the ALTGLASS database as a means of classifying glasses that with potentially anomalous durability responses; i.e., the phase separation discriminators provide a potential mechanistic explanation of PCT anomalies.

The original discriminator [18] was a probability function that determines if glasses are homogeneous based on the following criterion, where the more **negative the value**, the **less likely** the glass is to **phase separate**:

$$-1.6035x - 5.6478y + 210.9203 = P(x,y) \quad (2)$$

Where, P(x,y) is the criterion value and:

$$y = \text{Dense Oxide Components} \equiv Al_2O_3 + (Fe_2O_3 + FeO \text{ calculated as } Fe_2O_3) + Nd_2O_3 + Ce_2O_3 + La_2O_3 + Y_2O_3 + CaO + MoO_3 \quad \text{(wt.\%)}$$

$$x = \text{Less Dense Oxide Components} \equiv Na_2O + Li_2O + K_2O + Cs_2O + SiO_2 + B_2O_3 \quad \text{(wt.\%)}$$

There is an intermediate region, where the criterion value in Equation (2) may equal a value on the interval [-1,1]. If the discriminator criterion falls within this interval, this particular criterion is indeterminate, and more investigation is needed to determine if the composition is phase separated.

The use of this phase separation criterion in Equation 2 was later dropped in favor of an approach that ensured that the DWPF durability model would be linear in glass composition, which is an important factor in the error analysis within the DWPF process/product (P/P) models for process control. Rather than group glasses as "phase separated", "intermediate", or "homogeneous", these new constraints indicate if a glass composition's durability is predictable via the THERMO^{TM} model based on the potential for phase separation. Collectively referred to as the "reduction of constraints (ROC)", the criteria in use in DWPF during sludge-only processing [21] and in coupled processing [22] is currently defined as the following:

(1) an alumina constraint of $Al_2O_3 \geq 3$ wt.% and a sum of alkali constraint with an upper limit of 19.3 wt.% ($\Sigma M_2O < 19.3$ wt.%), or
(2) a lower limit on the Al_2O_3 constraint of 4 wt.% ($Al_2O_3 \geq 4$ wt.%) without a ΣM_2O

For glasses with $Al_2O_3 \geq 3$ wt.% and $\Sigma M_2O < 19.3$ wt.% or glasses with ≥ 4 wt.% Al_2O_3, phase separation is not problematic and the glass durability response is linear in glass composition. For glasses with Al_2O_3 of 3-4 wt.% and $\Sigma M_2O \geq 19.3$ wt.%, the homogeneity of the glass should be examined by various microscopy techniques to determine if the glass is phase separated and the durability response needs to be examined as durability becomes dependent on the glass composition and the solution pH. The pH of the corroding solution is directly proportional to the alkali content of the corroding glass, and durability is inversely proportional to solution pH [18]. For nuclear waste glasses with $Al_2O_3 < 3$ wt.%, the glasses are likely to be phase separated – independent verification is also suggested with electron microscopy or spectroscopic diffraction. These criteria have been included in previous versions of the ALTGLASS database.

In 2016, a TiO_2 criterion was added to the DWPF durability model, based on data that suggested glasses with $TiO_2 \geq 2.0$ wt.% could potentially phase separate if the Al_2O_3 content in the glass was less than 4.0 wt.% [25]. This TiO_2 criterion was added to this version of the ALTGLASS database. If $TiO_2 < 2.0$ wt.%, then the aforementioned criteria regarding Al_2O_3 content and the sum of the alkali oxides is used to indicate the predictability of a glass composition's durability based on potential phase separation issues. All of the current DWPF-based discriminators were combined into a single logical test that was also added to ALTGLASS Version 3.0. Table 5 summarizes the various discriminators that were added to the ALTGLASS database to facilitate glass dissolution modeling efforts.

Table 5: Information useful for subset classification is provided by the database in the form of the listed property states.

Property State	Database Definition
Phase-separated/homogeneous (Original THERMO™ discriminator)	$-1.6035x - 5.6478y + 210.9203 \begin{cases} < -1, \text{ HOMOGENEOUS} \\ > 1, \text{ Potential } \varphi\text{-sep.} \\ [-1,1], \text{ Indeterminate} \end{cases}$
Low or high alkali	Low alkali $\Rightarrow \Sigma_{alkali} < 19.3$ wt.% alkali High alkali $\Rightarrow \Sigma_{alkali} \geq 19.3$ wt.% alkali
Low/Mid/High Al_2O_3	Low Al $\Rightarrow Al_2O_3 < 3.0$ wt.% Mid Al $\Rightarrow 3.0$ wt.% $\leq Al_2O_3 < 4.0$ wt.% High Al $\Rightarrow Al_2O_3 \geq 4.0$ wt.%
Low/High TiO_2	Low Ti $\Rightarrow TiO_2 < 2.0$ wt.% High Ti $\Rightarrow TiO_2 \geq 2.0$ wt.%

All of the new compositions have been added to Table 9 in Appendix A. Note that the Environmental Assessment (EA) glass [23,24], which has Al_2O_3 ~3 wt.% and $\Sigma M_2O \geq 19.3$ wt.%, was extensively studied by microscopic methods to determine that it was not phase separated. This example with EA glass is highlighted to illustrate that the discriminators referenced here and extensively reported on in the given references are not necessarily wholly deterministic – some glasses that are indicated to be phase separated may, upon investigation, be determined homogeneous and at the same time the opposite may be true for other compositions. The information regarding phase separation is included in the database only to serve as a guide to modeling efforts should anomalous leaching behavior not fit a given model or approach and not to definitively designate glasses as "homogeneous" or "phase separated."

The cells with gray shading in Table 9 are compositional regions where glasses are expected to be homogenous based on the aforementioned ROC constraints. The regions with black shading are glass formulation regions where care must be exercised to determine the impact of potential phase separation and/or excess alkali on the glass durability. The unshaded region of glass formulation should be avoided during HLW and LAW glass formulation for long term durability concerns associated with potential phase separation. Table 10 gives a comparison between the ROC glasses that were determined to be predictable coupled with the criterion from the original homogeneity discriminator. Glass compositions in the shaded cell of Table 10 are considered to be agreeably homogeneous in that their P(x,y) is negative and they are considered "predictable" by the ROC criteria.

While a failure to meet the phase separation criteria excluded a glass's inclusion in the aforementioned DWPF modeling efforts, glasses that were potentially phase separated were not automatically excluded from the ALTGLASS database. Phase separated glasses, especially low alkali phase separated glasses, can be durable depending on the type of phase separation that occurs [12,18]. Therefore, the low alkali glasses, as well as the glasses with less than three weight percent Al_2O_3, are also gray-shaded in Table 9 in Appendix A.

3.3 Leachate Parameters

In the ALTGLASS database, the leachate parameters given in Table 6 were tabulated if available. Data for specific compositions or test durations were not entered into the database unless a minimum set of leachate parameters were available – these essential elements are shaded in Table 6. Some glasses did not contain Li_2O and/or Fe_2O_3, and for those glasses the minimum leachate parameters for Li and Fe concentration were nonexistent. Those glasses without Li_2O and Fe_2O_3 reported in the leachate were included in ALTGLASS, whereas a glass containing Li_2O and/or Fe_2O_3 that did not report the Li and Fe releases to solution were not included in the database. Data sets used in ALTGLASS had to contain Al or Fe or both in ppm in order to be included in the database due to the importance of these two components in the secondary phase formation on the glass surfaces that return to an accelerated rate. Because of these minimum requirements, many of the available data could not be included.

Table 6: Leachate parameters tabulated and minimum leachate requirements for inclusion in the database. Shaded cells represent elements that must be reported in the leachate concentration for a sample to be included in the database.

Leachate Parameter
pH
Si (ppm)
B (ppm)
Ca (ppm)
Li (ppm)†
Na (ppm)
K (ppm)
Al (ppm)†
Fe (ppm)†
Mo (ppm)
Mg (ppm)
Ti (ppm)
Zn (ppm)
Zr (ppm)
U (ppm)

†Unless a given glass did not contain these elements.

The ALTGLASS Version 3.0 database contains 2635 rows of data with each row representing the average of duplicate or triplicate PCT tests for over 500 different glasses. Averages of the individual PCT tests were used instead of singular measurements as many of the references only contained averaged results. In order to maintain consistent error structure in accordance with ASTM C1285-14 and eliminate weighting discrepancies during modeling, singleton (not duplicate or triplicate analyses) measurements were not included in the database.

Two sets of data in groundwater, one in Yucca Mountain J13 groundwater and one in SRS E-Area Groundwater, are located at the end of the database since these experiments were conducted under different initial conditions (i.e., leachant type) than the other experiments conducted in ASTM Type I water.

For several of the longest duration PCT tests, pH measurements were not available due to a lack of solution for analysis.

The ranges of leachate pH values and the concentrations represented by the leachates in the database are given in Table 7. As can be seen by inspection of Table 7, the ranges of measured leachate concentrations for the glass elements can vary by as much as four orders of magnitude implying that the database covers a broad spectrum of glass durabilities.

Table 7: Maximum and minimum (non-zero) concentration of measured leachate parameters.

Parameter	Min.	Max.
pH	7.39	13.66
Si (ppm)	2.260	45,200.00

3.4 Glass Parameters and Phase Identification

The compositions of glasses in ALTGLASS are given in oxide weight percent (wt.%). In addition, any experimentally observed glass alteration phases, formed as a result of corrosion phenomena, that were identified by x-ray diffraction (XRD) and/or scanning electron microscopy (SEM) were tabulated. The minimum and maximum glass compositions are given in Table 8. The compositions reported in the database are a combination of both target and measured values since measured glass compositions were not present in all the references used to compile the database. The target compositions of some glasses did not contain many of the species for which compositional columns are listed, such as BaO, Ce_2O_3, Li_2O, U_3O_8 or "others"; however, the minimum value for these oxides is not reported as zero but rather as the minimum measured concentration when that particular oxide *is* present in a glass. If the composition of the "others" component was not given in the references from which the data was taken, no additional information is available about the "others" compositions, and these data are not tabulated.

Table 8: The minimum and maximum compositional values of the glasses presented in ALTGLASS.

Oxide	Non-zero Min.	Max.
Al_2O_3	0.19	21.29
B_2O_3	0.10	18.48
BaO	0.01	1.34
CaO	0.01	12.81
CeO_2	1.10	2.07
Ce_2O_3	0.02	0.74
Cr_2O_3	0.01	1.14
Cs_2O	0.03	2.34
CuO	0.01	0.22
Cu_2O	0.11	0.20
FeO	0.07	8.81
Fe_2O_3	0.01	21.86
K_2O	0.01	8.08
Gd_2O_3	0.07	6.39
La_2O_3	0.01	1.94
Li_2O	0.00	14.67
MgO	0.02	7.70
MnO	0.03	3.34
MoO_3	0.01	3.53

Y_2O_3	0.02	0.47
ZnO	0.01	5.82
ZrO_2	0.01	6.12
Others	0.05	5.81

4.0 ALTGLASS Version 3.0 Updates

ALTGLASS Version 3.0 (Table 11) is the first issuance of the database to include a major subset of data from a foreign entity. Over 500 rows of data have been added in the newest release composed of entries including MAGNOX and Blend compositions from the NNL in the United Kingdom [26], glasses that were fabricated at the Savannah River National Laboratory and subjected to PCT analysis by NNL [27], Hanford low-activity waste (LAW) glasses that were fabricated and tested at PNNL [28,29], and LAW glasses that were tested by VSL [30].

5.0 Path Forward

Current efforts at SRNL are focused on applying informatics principles to a limited data subset of long-term HLW corrosion experiments in order to hypothesize the fundamental mechanisms responsible for various glass corrosion phenomena [31, 32]. The ALTGLASS database is central to the development of this statistical approach, and researchers have already used the informatics approach to establish a statistically significant correlation between leachate concentration data, such as those provided in ALTGLASS, and potential "trigger" mechanisms for Stage III corrosion.

Given the level of interest in developing glass dissolution models that can adequately predict the rate of radionuclide release at all stages of glass corrosion, longer term corrosion tests are required to provide a broader experimental reference for geochemical, chemical, and atomistic modeling. To date, only a limited number of corrosion experiments reported in the database have been conducted for sufficiently long duration to observe a resumption of glass alteration that is conducive with Stage III corrosion.

Additions will continue to be made to the ALTGLASS database as data becomes available from other groups, laboratories, and institutions within and outside of the United States. A new version of ALTGLASS will be released upon the accumulation of sufficient data to merit revision. SRNL will continue to be responsible for the maintenance and distribution of the database in electronic form upon request.
